Complex cellular automata a way to unconventional computing

Today, a “computer”, without further qualifications, denotes a rather well-specified kind of object; we’ll consider a computer “non-conventional” if its physical substrate or its organization significantly depart from this de facto norm. [Toffoli 1998]

Unconventional computers shall exploit molecular computing level, to increase the power of computation, velocity, and storage. Actually, the term about of *unconventional computing* or *natural computing* have a number of directions:

- quantum computing
- DNA computing
- reaction-diffusion computing
- reversible computing
- tiling (pattern) computing
- origami computing
- Pysarum computing
- swarm computing

Dynamics in one dimension

boundary limit define a ring

Elemental CA (ECA) is defined as follows:

- $\Sigma = \{0, 1\}$
- $\mu = (x_{+1}, x_0, x_{-1})$ such that $x \in \Sigma$
- $\phi : \Sigma^3 \rightarrow \Sigma$
- $\mu = \{c_0 \mid x \in \Sigma\}$ the initial condition is the first ring with $t = 0$

Elementary cellular automaton rule 54

Some interesting points in rule 54:

- Artificial life
- Complex systems
- Logical computation
- Garden of Eden configurations
- Symmetric evolutions
- Guns emerge from random conditions

1900 cells x 1640 times

Particles are strings

The formal languages theory provides a way to study sets of chains from a finite alphabet. The languages can be seen as inputs for some classes of machines or as the final result from a typesetter substitution system i.e., a generative grammar into the Chomsky's classification. This way, following a variation of a Feynman diagram hence we can represent collisions between particles in one-dimensional cellular automata as follows.

- p, q, δ – particles
- e – periodic background
- \square – phase
- $f(p, q) \rightarrow \delta$

Particles are strings: Doug Lind starts this representation in ECA from 1986

Revised Manuscript to be reviewed

The previous two pages show patterns produced by evolution according to rule 110, starting from a 1-dimensional initial configuration. The first picture shows all sites on a row of 400 lattice. The second picture shows every other site is open and none on a row of 800 lattice.

The configuration produced after many steps can be represented in terms of particles (the markers) superimposed on a periodic background. The background is fixed in time (equal period) in our original period T , and corresponds to a sequence of the block $\Phi = 1000101111000$. The configurations are then of the form $\cdots \Phi\Phi\Phi\Phi\Phi\Phi\cdots$, where the particles Φ that have been found so far are

The 'industry' is written as repeated period/temporal periods.

The only question that the literature of this field is sophisticated enough to regard as a real question.

Table 1 of particularity by Group (Lack of Mathematics Department, University of Washington, Seattle)

Particles are strings and filters: James Hanson and James Crutchfield describing finite state machines in ECA from 1997

Fig. 10 shows the domain map $\mathcal{D}_{\text{dom}}^{\text{dom}}$ which maps each of the domains in \mathcal{D} and each vertex in \mathcal{V} to a unique vertex in $\mathcal{D}_{\text{dom}}^{\text{dom}}$. The labelled vertices are mapped to the domain map in Fig. 1.

Fig. 10. Space-time plot of Fig. 1, filtered with the discrete threshold $T_{th} = 4$ (Fig. 1). White cells correspond to the partitioning of A_{t+1} into cells for state partition $\alpha \in \{1, \dots, 6\}$.

Figure 1.22: The de Bruijn diagram for evolution to the constant 1 after six generations.

Particles as strings from finite states machines

For an one-dimensional cellular automaton of order (k,r) , the *de Bruijn diagram* is defined as a directed graph with k^{2r} vertices and k^{2r+1} edges. The vertices are labeled with the elements of the alphabet of length $2r$. An edge is directed from vertex i to vertex j , if and only if, the $2r-1$ final symbols of i are the same that the $2r-1$ initial ones in j forming a neighbourhood of $2r+1$ states represented by $i \diamond j$. In this case, the edge connecting i to j is labeled with $\phi(i \diamond j)$.

The connection matrix M corresponding with the de Bruijn diagram is as follows:

$$M_{i,j} = \begin{cases} 1 & \text{if } j = ki, ki + 1, \dots, ki + k - 1 \pmod{k^{2r}} \\ 0 & \text{in other case} \end{cases}$$

Basins of attraction or cycle diagrams calculate attractors in a dynamical system, as was extensively studied by Andrew Wuensche in CA and random Boolean networks. Given a sequence of cells x_i we define a configuration c of the system. An evolution is represented by a sequence of configurations $c_0, c_1, c_2, \dots, c_{m-1}$ given by the global mapping,

$$\Phi : \Sigma^n \rightarrow \Sigma^n$$

and the global relation is given for the next function between configurations,

Particles as strings from finite states machines

De Bruijn diagram (displacement 4, period 8)
calculating non-stationary particles in rule 110.
The left evolution displays a *fuse pattern*
produced by two particles colliding and both
annihilated. The center evolution displays a
periodic pattern and the right evolution displays
particles with displacement to the left.

$$N = \{61166, 56799, 48059, 30583, 61167, \\ 56703, 48062, 30589, 61178, 56821, 48107, \\ 30679, 61369, 57183, 48830, 32125, 64250, \\ 62965, 60395, 55255, 44975, 24415\}$$
$$((0111)^* + 11(01011111)^*)^*$$

It is an expression to codify A and B particles.

Particles as strings from finite states machines

Attractor length 31, period 7, with a mass of 5.487×10^7 configurations for rule 110. This attractor is in a field of 6,326 basins.

$w_0 = 0110111111110001001101111100010$
 $w_1 = 1111100000010011011111000100110$
 $w_2 = 1000100000110111110001001101111$
 $w_3 = 1001100001111100010011011111000$
 $w_4 = 1011100011000100110111110001001$
 $w_5 = 1110100111001101111100010011011$
 $w_6 = 0011101101011111000100110111110$

They are expressions to codify stationary (Cs) particles.

Circular computation

We have two important previous results in computer science theory to think about of circular computation. Arbib presents a circular Turing machine in 1962 and Kudlek and Rogozhin presents circular Post machines in 2001.

- a_i, h : symbols
- h : the limit of the type
- p_k : state
- \rightarrow : head

Important features: (1) label and limiting the end of the type, (2) the movement is turning the type, (3) the type can introduce new squares.

- Arbib, M.A. (1962) **Monogenic Normal Systems are Universal**, Monogenic normal systems are universal. Journal of the Australian Mathematical Society, 3(3) 301-306.
- Kudlek, M. & Rogozhin, Y. (2001) **Small Universal Circular Post Machines**, Computer Science Journal of Moldova 9(1) 34-52.

Symbol super colliders (Tommaso Toffoli, 2002)

In 2002, Toffoli exposed the concept of “symbol super collider”. To map Toffoli's supercollider onto a one-dimensional cellular automata we use the notion of an idealized particle $p \in \mathbb{Z}^+$ (without energy and potential energy). The particle p is represented by a binary string of cell states. Typically, we can find all types of particles manifest in cellular automata particles, including positive p^+ , negative p^- , and neutral p^0 displacements, and also composite particles assembled from elementary particles.

(a) $f(u, v)$ is a product of one collision

(b) $f(u, v) = u + v$ union

(c) $f_i(u, v) \mapsto (u, v)$ identity

(d) $f_r(u, v) \mapsto (v, u)$ reflection

(a)

(b)

(c)

(d)

Schemes of ballistic collisions between particles evolving in *cyclotrons*. Gray circles represent the contact point of collision.

Symbol super colliders

Transition between two beam routing synchronizing multiple reactions. When the first set of collisions are done a new beam routing is defined with other particles, so that when the second set of collisions is done then one returns to the initial condition of the first beam, constructing a meta-glider or mesh in Rule 110.

In this way, we can design more complex constructions synchronizing multiple collisions with a diversity of speeds and phases on different particles. Figure displays a more sophisticated beam routing design, connecting two of beams and then creating a new beam routing diagram where edges represent a change of particles and collisions contact point on ECA Rule 110. In such a transition, a number of new particles emerge and collide to return to the first beam, thus oscillating between two beam routing forever.

$$p_A^+, p_A^+ \leftrightarrow p_B^-, p_B^-, p_B^-$$

changing to the set of particles (second beam routing):

$$p_{A^4}^+ \leftrightarrow p_E^+, p_E^+$$

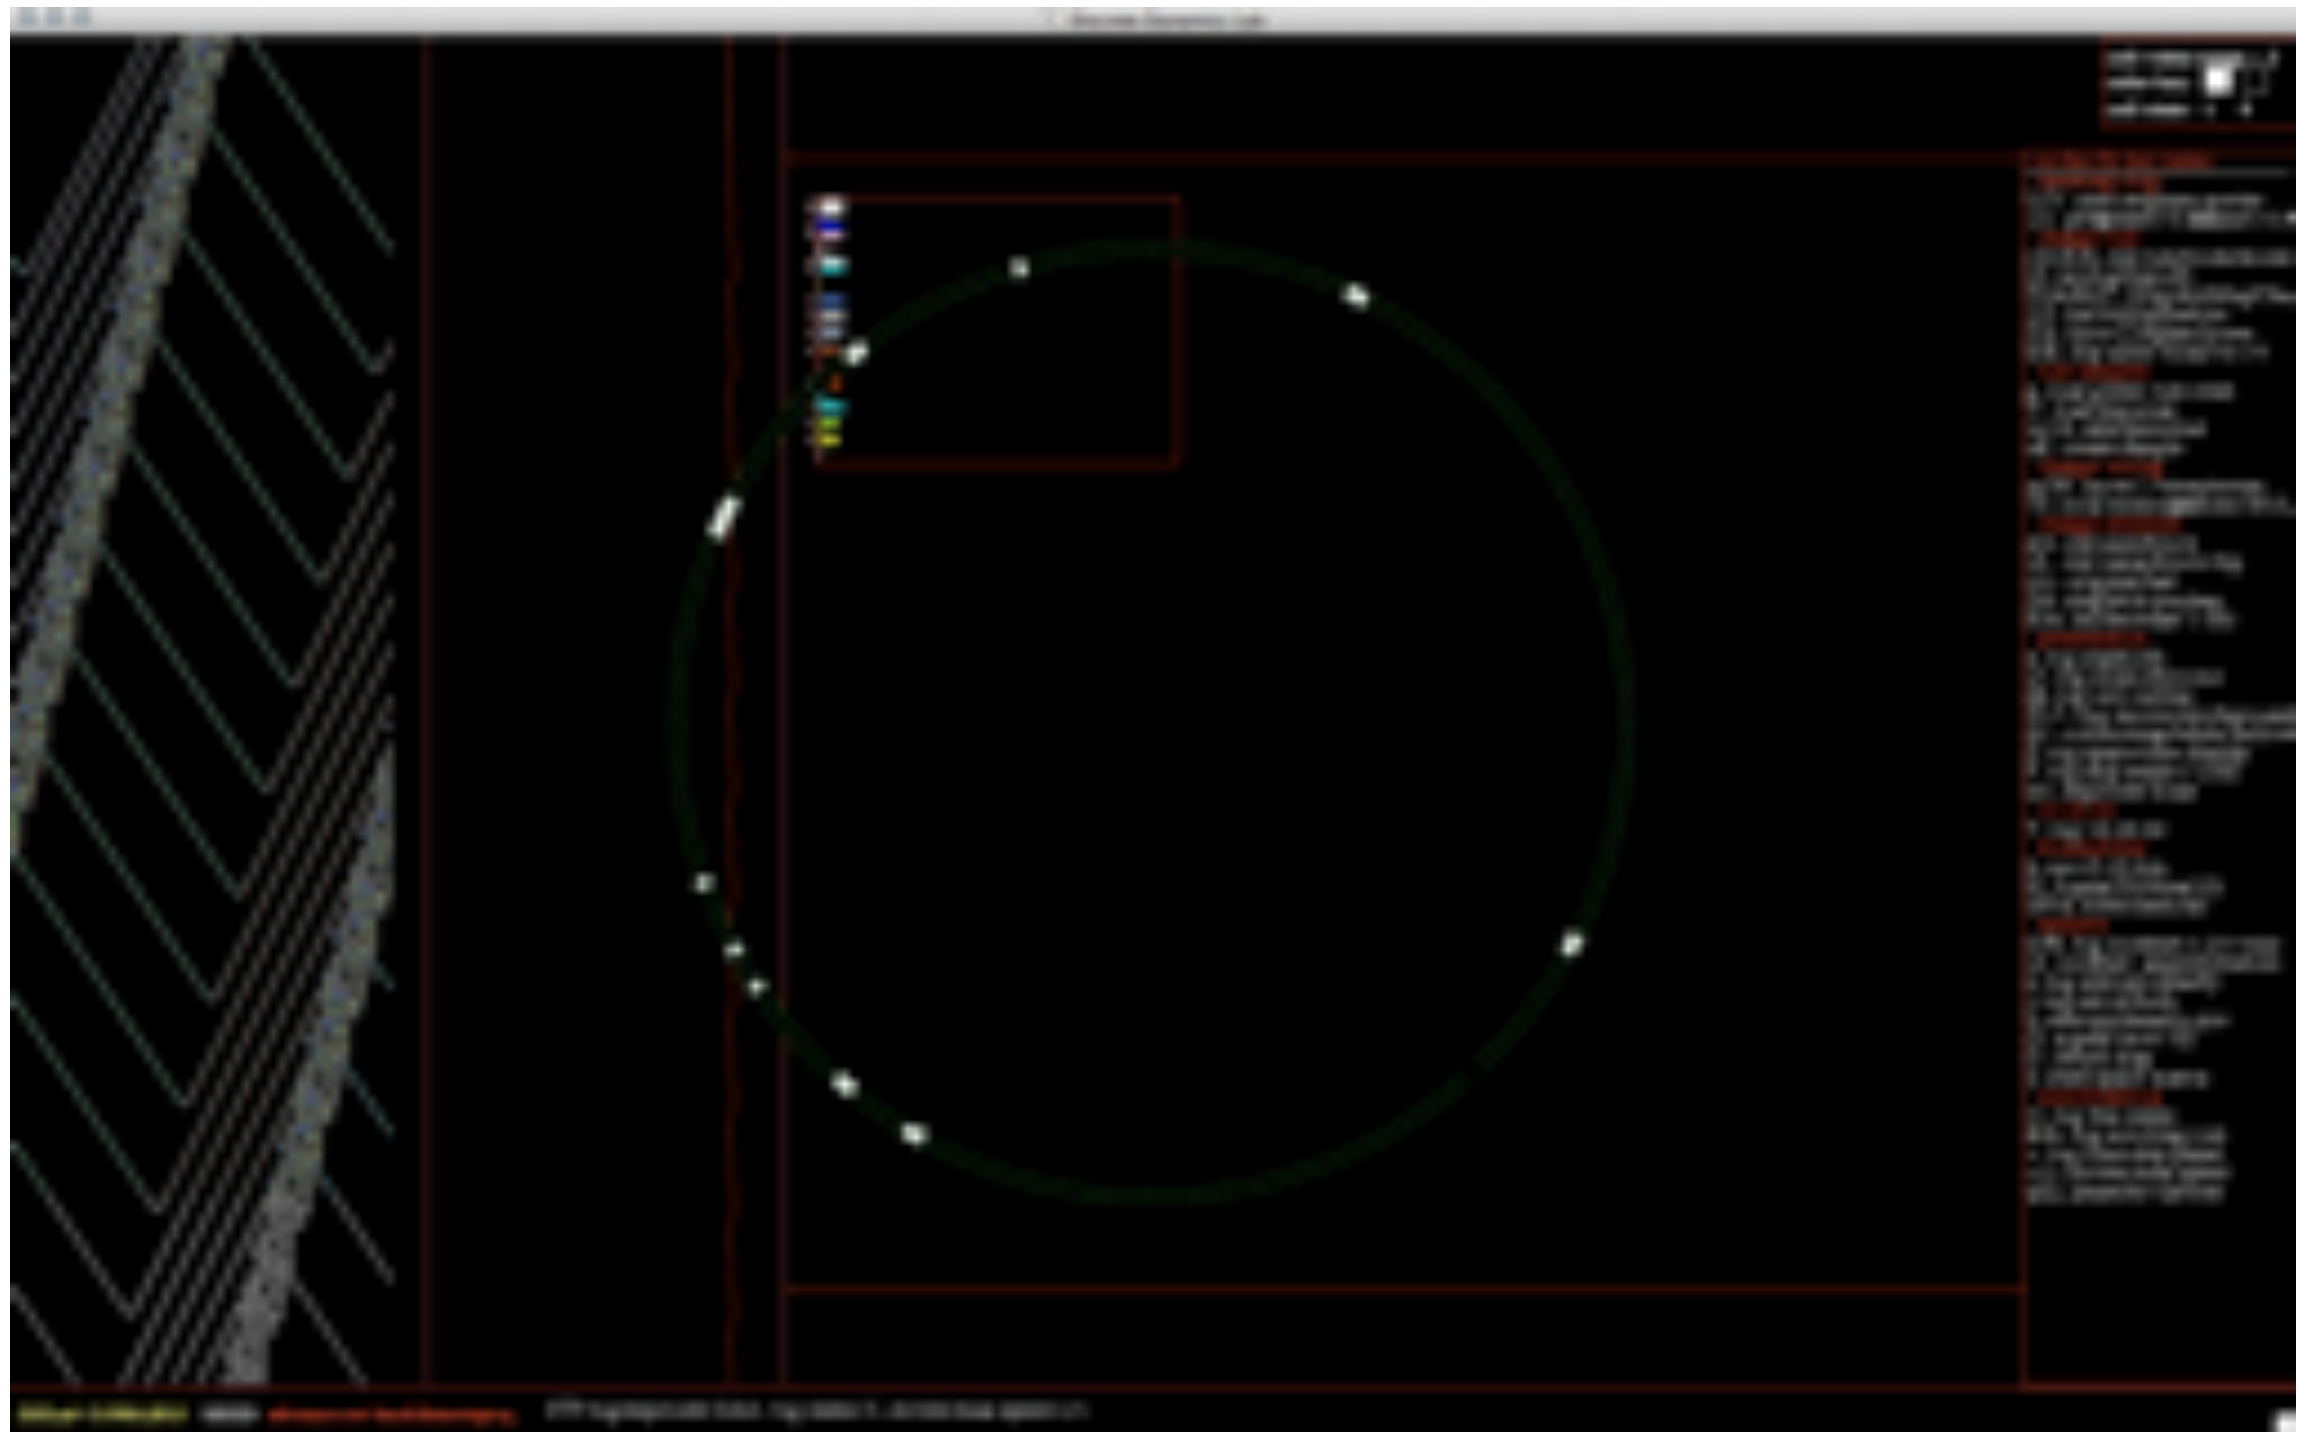

defining two beam routing connected by a transition of collisions as:

$$(p_A^+, p_A^+ \leftrightarrow p_B^-, p_B^-, p_B^-) \rightarrow (p_{A^4}^+ \leftrightarrow p_E^+, p_E^+), \text{ and} \\ (p_{A^4}^+ \leftrightarrow p_E^+, p_E^+) \rightarrow (p_A^+, p_A^+ \leftrightarrow p_B^-, p_B^-, p_B^-).$$

DDLab evolving cellular automata as rings (cyclotrons)

Cyclotrons are the first stage where we can see periodic collisions or simple dynamics of particles traveling around the ring.

A multiple collision between eight particles we can produce a glider gun in rule 110. In this simulation using DDLab, we can see the typical two dimensional representation and at the center the cyclotronic view, with the periodic background filtered.

Construction of patterns by synchronization of multiple collisions in rule 54

Using a cyclotron we can design patterns with other views. This simulation starts with an initial condition of 3,214 cells codifying 216 particles in rule 54. The reaction is a triple collision controller by two basic interactions:

$$f(g_e, \overleftarrow{w}) \rightarrow \overleftarrow{w}, g_e, 2\overrightarrow{w} ; f(2\overrightarrow{w}, \overleftarrow{w}) \rightarrow \overleftarrow{w}$$

The reaction starts with a negative particle w colliding versus a stationary particle g yielding a negative particle plus two positive particles w . But the first negative particle finds these new pairs of positive particles and annihilate them.

Therefore, we can codify these particles with the next expression: $(\overleftarrow{w}-2e-g_e(A,f_1)-2e-\overleftarrow{w})^*$.

Cyclic tag systems in a finite codification as a collider

This way, the cyclic tag system working in rule 110 can be simplified as follows:

left: $\{649e-4_A^4(F_i)\}^*$, for $1 \leq i \leq 3$ in sequential order

center: $246e-1Ele_C2(A,f_1-1)-e-A^3(f_1-1)$

right: $\{\text{SepInit_}E\bar{E}(\#,f_i-1)-1\text{BloP_}\bar{E}(\#,f_i-1)-\text{SepInit_}E\bar{E}(\#,f_i-1)-1\text{BloP_}\bar{E}(\#,f_i-1)-0\text{Blo_}\bar{E}(\#,f_i-1)-1\text{BloS_}\bar{E}(\#,f_i-1)\}^*$ (where $1 \leq i \leq 4$ and $\#$ represents a particular phase).

This way, we have that the string $w_{CTSR110}$ is a word able to simulate a finite state machine into a cellular automata collider.

$$w_{CTSR110} = (649e \cdot 4_A^4(F_i))^* \cdot (246e \cdot 1Ele_C2(A,f_1-1) \cdot e \cdot A^3(f_1-1)) \cdot (\text{SepInit_}E\bar{E}(\#,f_i-1) \cdot 1\text{BloP_}\bar{E}(\#,f_i-1) \cdot \text{SepInit_}E\bar{E}(\#,f_i-1) \cdot 1\text{BloP_}\bar{E}(\#,f_i-1) \cdot 0\text{Blo_}\bar{E}(\#,f_i-1) \cdot 1\text{BloS_}\bar{E}(\#,f_i-1))^*.$$

A diagram of a cyclic tag system (CTS) working in rule 110

Final remarks

Complex ECA rules with different capacities explored with cyclotrons.
